Executive Summary

This report presents the validation results for the Copernicus Land Monitoring Service (CLMS) raster product CLCplus Backbone (CLCplus BB) 2018. It comprises a raster inventory layer displaying the predominant land cover class out of 11 basic categories for the reference year 2018. The work was conducted under the framework service contract No EEA/DIS/R0/23/010. Thematic accuracy was assessed in a statistically sound approach using available reference and supportive data at different reporting units. It shows that

- **Results are good but fall short of the target >90% at EEA38** reporting level with blind validation at 77.2% (0.6% Margin of Error) and plausibility validation at 85.2% overall accuracy (0.5% Margin of Error). Classes such as low-growing woody plants (5), lichens and mosses (8), and non- and sparsely-vegetated (9) showed significant improvement during plausibility checks.
- **There are some differences** at the Biogeographical Region level (BGR). The Arctic (ARC) region is the only one to achieve >90% overall accuracy (90.2%), lowest accuracy is observed in the Tropical (TRO) region (74.4%). The Mediterranean (MED) and Tropical regions (TRO) show significant challenges to distinguish low-growing woody plants (5), permanent herbaceous (6) and periodically herbaceous (7).

The CLMS Portal shows a good level of accessibility and usability, satisfying the essential user requirements for data access, multi-format availability, and protocol standards. It is recommended that optional metadata elements are included to facilitate more sophisticated chatbot interactions. To enhance usability and reproducibility in future product data releases, selected optional metadata elements could be refined.

Based on an analysis of product manuals and production-internal verification, a product requirements assessment was conducted based on the use case “Facilitation of independent assessments and the modelling of carbon pool dynamics according to LULUCF regulation”.

A review of the documentation confirmed the availability of a comprehensive and detailed Product User Manual (PUM), which covers all necessary features. In future PUM releases there are a few areas that could benefit from improvement and the newly developed CLMS PUM template and guidance could be employed to ensure that the CLMS product documentation is consistently presented to users.

NOTE:

This report is intended to serve as the primary source for the information on thematic accuracy and selected usability aspects of CLCplus Backbone 2018 (raster) and contains the results from an independent, post-hoc assessment. A previous assessment of thematic accuracy that served production quality control ('internal validation') is presented within the Product User Manual of CLCplus Backbone 2018 (v3.0). Differences between the two assessments that result from different study designs, sample interpretation, the reference data considered as well as reporting levels and metrics are acknowledged but not further analysed here.

1 Introduction

This report informs about the validation assessments and their results obtained for the CORINE Land Cover plus Backbone (CLCplus BB) raster product 2018. The validation was conducted under the framework service contract No EEA/DIS/R0/23/010. The CLMS validation framework defines the validation methods applicable to the different CLMS products in a way to maximise synergies, yet also allow adaptations needed to product specific characteristics. Generally, the validation framework addresses the different validation elements referred to in the ISO19157:2023 standard, titled "Geographic information -- Data quality", to investigate the CLMS product quality within the CLMS validation framework:

- **Completeness:** The presence and absence of features, their attributes, and relationships.
- **Logical consistency:** The degree of adherence to logical rules of data structure, attribution, and relationships (e.g., topological consistency).
- **Positional accuracy:** The accuracy of the position of features.
- **Temporal accuracy:** The accuracy of temporal attributes and the relationships of features with time.
- **Thematic accuracy:** The accuracy of attribute values and classifications.

In addition to the ISO19157 quality elements:

- **Usability:** Checks assess the alignment of the product and metadata with FAIR (Findability, Accessibility, Interoperability, and Reusability) principles, as well as the quality and completeness of product documentation. Additionally, product specifications are evaluated against requirements derived from the specific use case: "Facilitating independent assessments and modelling carbon pool dynamics according to LULUCF regulation".

Completeness, logical consistency and positional accuracy are tested and validated as part of the CLMS production and delivery phase, mainly via the CLMS QC Tool (*CLMS QC Tool*, 2025) and are not replicated here. Temporal accuracy checks are only applied to CLMS product layers, where the relationships of product features to time are an implicit product criterion and where not applied for the CLCplus BB 2018 raster product.

2 Product Description

CLCplus BB is a detailed pan-European wall-to-wall land cover (LC) inventory layer. It is part of the CLCplus product suite. This validation report covers the CLCplus BB product generated for the reference year 2018 (Table 1). The product provides, as a 10m spatial resolution raster layer, 11 encoded LC classes (Table 2) according to a predefined product specification (Table 2).

Table 1: CLMS product elements validated

Product Name	Acronym	Version	Date Provided / Published
CLCplus Backbone Raster	CLCplus BB 2018	V1_1	23.01.2023 (Publication)

Table 2: CLCplus BB 2018 raster product characteristics (Copernicus Land Monitoring Service, 2022)

Product Name	Acronym	Product family
CLCplus Backbone Raster Product 10m	CLCplus BB 2018	CLMS_CLCplus
Summary	CLCplus Backbone is a spatially detailed, large scale, EO-based land cover inventory. The CLCplus Backbone Raster Product is a 10m pixel-based land cover map based on Sentinel time series from June 2017 to June 2019 and auxiliary features. For each pixel it shows the dominant land cover among the 11 basic land cover classes.	
Reference year	2018	
Geometric resolution	Pixel resolution 10m x 10m, fully conform with the EEA reference grid	
Coordinate Reference System	European ETRS89 LAEA projection / for French DOMs WGS84 and the respective UTM zone	
Coverage	6.002.168 km ² (covering the full EEA38 + UK)	
Geometric accuracy (positioning scale)	Equals Sentinel-2 positional accuracy in 2018 (~ 11m at 95.5 % confidence level)	
Thematic accuracy	90 % overall accuracy, not more than 15 % omission errors and 15 % commission errors per class (the amount of omission and commission errors for particular difficult classes such as Low-growing woody plants and Lichens and Mosses might regionally exceed those thresholds)	
Data type	8bit unsigned raster with LZW compression	
Minimum Mapping Unit (MMU)	Pixel-based (no MMU)	
Raster coding (thematic pixel values)	1: Sealed 2: Woody – needle leaved trees 3: Woody – Broadleaved deciduous trees 4: Woody – Broadleaved evergreen trees 5: Low-growing woody plants (bushes, shrubs) 6: Permanent herbaceous 7: Periodically herbaceous 8: Lichens and mosses 9: Non- and sparsely-vegetated 10: Water 11: Snow and ice 254: Outside area 255: No data	
Metadata	XML metadata files according to INSPIRE metadata standards	
Delivery format	GeoTIFF incl. pyramids and INSPIRE-compliant metadata in XML format

3 Validation Methodology and Analysis

The following chapters describe the specific methods to check the thematic accuracy and usability for the CLCplus BB product 2018.

3.1 Thematic Accuracy

The CLMS validation approach for thematic accuracy compares the CLMS products with validation data in a sample-based approach, following established scientific practices (Congalton & Green, 2008; Olofsson et al., 2014; Stehman & Foody, 2019). The validation data is assumed to be more accurate than the product data. The level of agreement between validation and product data defines the thematic accuracy. The accuracy estimation methodology consists of three major components, explained in more detail in the following chapters: Sampling Design, Response Design and Accuracy Assessment.

3.1.1 Sampling Design

The sampling design involves the protocol for selecting the sample and determining the number of sample units. The sample is chosen using a probability approach, ensuring each element has a calculable chance of selection (sampling weights). This approach allows for extrapolation of accuracy from the sample to the entire study area. Stratification is used to effectively allocate samples to classes of interest or rare classes that might otherwise be underrepresented. Knowing the sampling probability (weights) is crucial to account for unequal probabilities and prevent bias in accuracy estimation. **The sampling design for the validation of thematic accuracy for the CLMS product consists of two elements** (Figure 2):

- **Validation Areas:** representing the smallest reporting unit and seamlessly covering EEA38 territory as defined by the Copernicus EEA38 boundary layer (EEA, 2023)
- **Sampling Frame:** 2x2 km grid points covering all validation areas

The validation areas are primarily defined by NUTS2 administrative units, which provide comprehensive and scalable coverage for the validation process. They are aligned with the CLMS production extent, including a buffer around the terrestrial territory. The validation areas are stratified by the Biogeographical Regions (BGR) dataset by the EEA (EEA, 2016). It contains the official delineations used in the Habitats Directive (92/43/EEC) and for the EMERALD Network set up under the Convention on the Conservation of European Wildlife and Natural Habitats (Bern Convention). Each validation area is assigned to the BGR where the majority of the territory overlaps. During the generation of the validation areas, smaller NUTS2 units with fewer than 500 sample grid points were aggregated, and larger NUTS2 units were split to better align with the boundaries of the BGR.

The sampling frame is represented by points along a 2x2 km-spaced grid aligned with the Copernicus grid (EEA, 2024) and LUCAS Master frame grid (Ballin et al., 2018). It was spatially enlarged to cover EEA38 and each point of the grid is stratified by the CLCplus BB 2018 raster land cover class into 11 classes, with the pixel northeast of the point used as a reference class for stratification. The points define the position of the sample unit. The final sample units for the accuracy assessment are then selected using both validation areas and sampling frame.

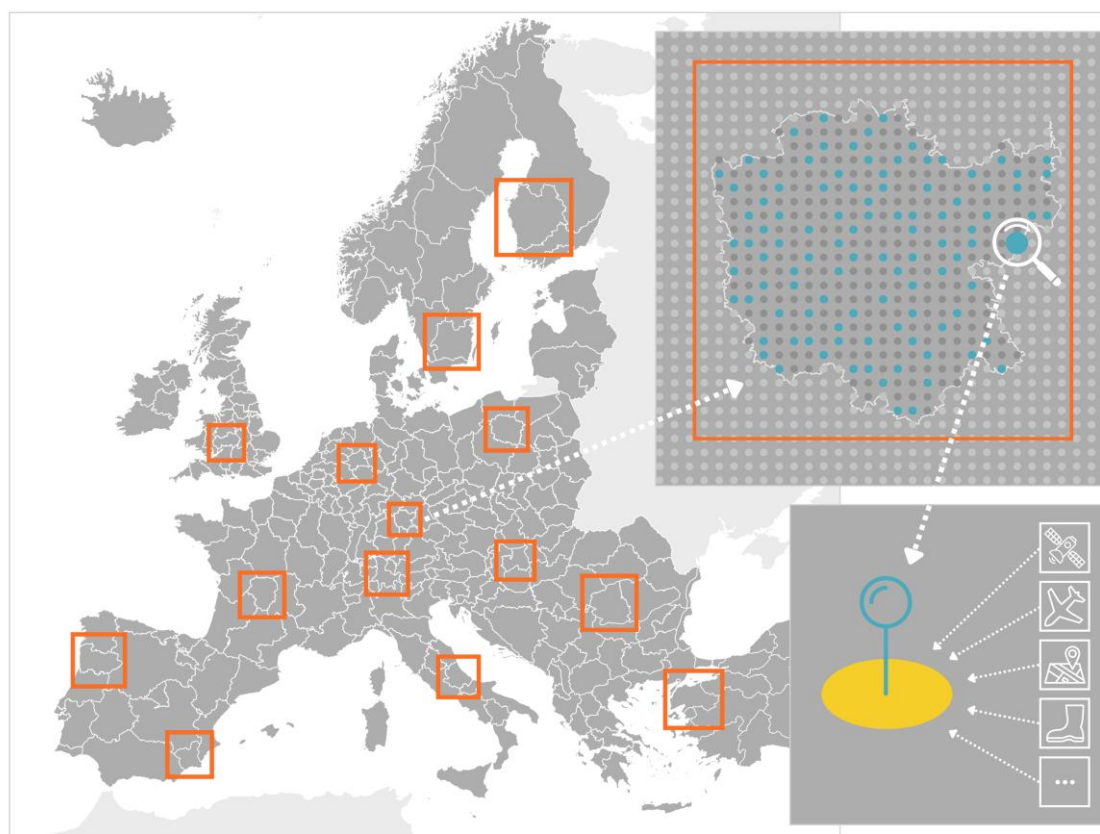

Figure 2: Schematic example of sampling design: selection of validation area (orange squares), selected sampling locations (blue) within validation area (white outline) and sampling units (yellow) populated with existing reference information.

The validation areas are selected from each BGR stratum using a random selection process, whereby larger validation areas are more likely to be selected. A minimum of one validation area per BGR is required, with an approximately proportional allocation of the remaining areas. Depending on the applied reporting level different numbers of validation areas are selected for the standard CLMS cross-cutting validations. For the EEA38 wide assessments of the CLCplus BB 2018, 38 validation areas are selected representing approximately 19% of EEA38 territory.

Adjustments are made to the initial selection in case of significant differences in reference data availability—such as when recent orthophotos are available in an alternative validation area within the same BGR. This is a pragmatic approach to cope with varying reference data availability across EEA38 while maintaining, as far as possible, the overall statistical validity of the sampling design.

Table 3: Validation areas per Biogeographical Region in EEA38

Biogeographical Region	EEA38	
	Total validation areas	Selected validation areas
Alpine (ALP)	21	3
Anatolian (ANA)	11	2
Arctic (ARC)	1	1
Atlantic (ATL)	42	6
Black Sea (BLS)	6	2
Boreal (BOR)	17	3
Continental (CON)	102	10

Biogeographical Region	EEA38	
	Total validation areas	Selected validation areas
Macaronesia (MAC)	2	1
Mediterranean (MED)	60	6
Pannonian (PAN)	10	2
Steppic (STE)	1	1
Tropical (TRO)	3	1
Total	276	38

Sample points are then drawn from the sampling frame within the selected validation areas.

The points are selected using a random stratified approach from each CLCplus BB 2018 strata.

The number of sample units is determined based on two key considerations:

- Minimum number of sample units for accuracy reporting: A sufficient number of sample units is needed to report accuracy across all thematic classes at both the validation area and BGR levels. The number of sample units is guided by the product accuracy requirements and corresponding margin of error (MoE) of $\pm 5\%$ at a 95% confidence interval. The underlying sample size calculation is presented in ((Olofsson et al., 2014) and uses expected user's accuracy p and targeted MoE d , to estimate the required number of sample units per class n_h . The z-score z is set to 1.96 for a 95% confidence interval.

$$n_h = \frac{z^2 p(1 - p)}{d^2}$$

- Based on the assumption of a product per class user's accuracy (UA) of 85% and a target MoE of the UA of 5%, this would then require 200 sample units per class. The objective is to have a minimum number of sample units per class at the BGR level. For each selected validation area there should be a minimum of 30 samples per class. However, fewer samples may be acceptable for rare classes that are not well-covered in some BGRs or validation areas. For some classes, the selected sample size is thus below 200 per BGR because there are not enough sample units available within the standard 2x2 km sampling frame.
- A maximum number of sample units per validation area was defined, ranging from 500 to 800, depending on the number of validation areas per BGR. Larger BGRs were allocated fewer sample units per validation area, while smaller BGRs with fewer validation areas received more. Once the minimum number of sample units per validation area is met, the remaining units up to the maximum number are allocated proportionally. This approach targets enough sample units for all thematic classes across all reporting levels, while maintaining a representative character by allocating a part of the sample units proportionally.
- Shared sampling design: The overall CLMS validation framework foresees that one sample can be used for different CLMS products (cross-cutting efficiency). To achieve this, a sufficient number of sample units must be allocated across different thematic domains. The CLCplus BB 2018 classes are used as the strata for guiding this allocation since its thematic classes cover most land cover types. To ensure adequate representation of rare classes, more sample units are included than typically required to achieve statistical robustness.

Sample weights are calculated for each sample unit combining the selection probabilities of the first stage and second stage sampling. The weights provide the information how many sample units each point represents in the total population of all possible sample points. It considers the different selection probabilities in both sampling phases and compensates for unequal number of samples per strata.

This general cross-cutting sampling approach foresees using the same validation areas and sample units for the validation of different CLMS products and reference years. Validation areas are not considered fixed but may be adjusted or changed in the course of later validation activities in order to consider the availability of existing and upcoming reference data, align with changing CLMS product extent or to better cover specific CLMS product classes.

Adjustments are needed to this general sampling approach for the CLCplus Backbone 2018 validation to ensure independence of validation data from production data. The LUCAS 2018 survey data has been used extensively in the production of CLCplus BB 2018 (Copernicus Land Monitoring Service, 2022), but is also an important reference data source for the CLMS validation. Therefore, to maintain independence from the training data, any point in the sampling frame grid that coincided with LUCAS 2018-point locations has been replaced using the following procedure:

- Shift the points 1 km north. If the point remains within the same CLCplus BB 2018 strata, it is kept in its new position.
- If the point does not remain in the same strata, shift the point 1 km east from the original position. If the point is within the same CLCplus BB 2018 strata, it is kept in its new position. If not, shift the point back to the northern position and accept the different strata.

This procedure ensures the independence of validation data by avoiding bias from using training data and maintains an approximate share of the same CLCplus BB 2018 strata. Around 26% of the sample points selected were shifted spatially.

The targeted sample size of 200 sample units is achieved for all thematic classes at the EEA38 level, except for the snow and ice class (11) (Table 4). For some biogeographical regions, there are thematic classes with lower sample unit numbers, due to their limited occurrence, e.g. sparse vegetation (9) in the Pannonian region (PAN), broadleaved evergreen trees (4) in the Black Sea region (BLS), or sealed areas (1) in the Arctic region (ARC).

Table 4: Sample units per CLCplus BB 2018 class and Biogeographical Region at EEA38

3.1.2 Response Design

The response design describes all steps to collect validation data at the sample sites and compare it with the product to be validated. It includes deciding on an appropriate type of sample unit and the protocol for collecting or preparing reference data to create a 1:1 spatial, thematic, and temporal match with the product data.

The sample unit for CLCplus BB 2018 consists of four pixels representing an area of 20x20 meters around the central sampling point (Figure 3). The north-eastern (NE) pixel is used as the main sample unit for Land Cover (LC) interpretation. Additionally, it is recorded if the other three units also belong to the NE-recorded LC. This enables further analyses, such as LC homogeneity assessments over the enlarged sample unit. In analogy to the CLCplus BB production process, a pixel is classified into a LC class if that class covers more than 50% of the pixel. If no single LC class exceeds 50%, a relative majority is used, as detailed in the decision tree applied during the CLCplus BB 2018 production (Copernicus Land Monitoring Service, 2024).

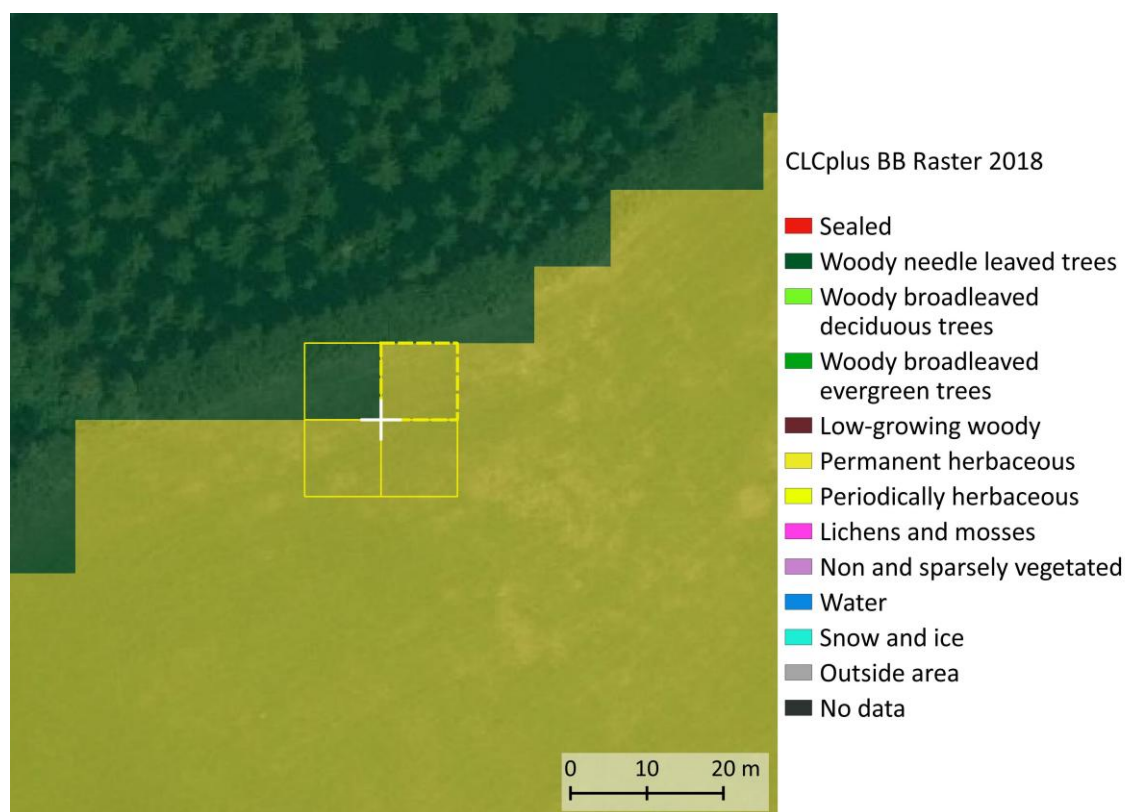

Figure 3: Sample units for the validation of CLCplus BB 2018. Central sampling point (white cross) and surrounding sample units (yellow) including the main North-Eastern sample unit (dashed line)

Validation data is created by classifying samples according to the thematic classes of the products being validated. This process involves utilizing existing and suitable datasets. **Sample units are inspected or visually interpreted using Computer-Assisted Photointerpretation (CAPI) and existing high quality reference and supporting data** (Table 5). The reference data serve as the primary source for visual interpretation, providing high-quality reference information from the same year. Supportive data, on the other hand, offer additional context or information to aid the decision-making process. Data from different years can be used to confirm stable classes/quantities from logical rules or to track and confirm change between CLMS product releases. For example, orthophotos showing deciduous forest in pre-product dates and deciduous forest in post-product years, imply that the same forest cover was also present in the in-between CLMS product reference year. The checks and interpretation of the sample units are conducted in a Geographic Information System (GIS) environment, employing dedicated data entry forms that incorporate a range of features including dropdown menus, checkboxes, comment text fields and the capacity for structured and guided data entry (Figure 4).

Figure 4: Standard GIS layout for interpretation of CLCplus BB sample units. Customised attribute entry form (right) and multiple maps views with reference or supportive layers (left).

To address possible discrepancies in temporal, thematic, or spatial comparability with validation data, two approaches are applied for validation:

- **Initial Blind Approach:** At this stage, validation data is created independently of the product. The interpreter is unaware of the CLMS product value or the sample strata to which it belongs to during the classification process, ensuring an unbiased comparison. Alternatively, reference data from different sources can be compared directly to the map. This approach helps to maintain the objectivity of the validation process.
- **Plausibility Approach:** In this phase, "not matching" sample units are reviewed again with knowledge of the CLMS product value. This review helps identify and rectify discrepancies due to factors such as border cases, ambiguous class definitions, or different minimum mapping units or issue related to positional shift between reference and map data (Table 6).

This approach results in two validation datasets, one from the initial blind approach and another after the plausibility review, thereby reducing errors in sample unit classification. The workflow ensures that the plausibility review is conducted only after the blind approach has been completed, and it is performed by a different operator, further enhancing the objectivity and accuracy of the validation process.

Table 5: Reference (r) and supportive data (s) used for the validation of CLCplus BB 2018

Coverage	Use	Product name	Reference type	Reference year	Access mode	Provider

Table 6: Possible causes for implausibility of CAPI blind results

Cause for blind CAPI not plausible	Explanation
Border case	Mixed pixels commonly found in transition zones between land cover types. Determining the precise coverage of a LC class is difficult. In such cases, the sample unit is classification "in favour" of the map.
Qualitatively limited reference data	The limitations of the reference data prevent an unambiguous classification. These limitations can be due to shift, tilt, shadow, low resolution, or partial missing data.
Difficult class elements for photointerpretation	LC difference cannot be directly interpreted. For example, the height of the woody plants distinguished CLCplus BB class 2/3/4 vs. 5. This attribute cannot be clearly determined from 2D image data. For the class 9 vs. 11, the duration of ice coverage in the course of the reference year is important and needs a time-series image interpretation.
Error in blind approach	Incorrect interpretation during blind approach.
Other/unclear	All other cases. Requires explanatory comment.

3.1.3 Accuracy Assessment

The product's thematic accuracy is assessed by comparing the validation data and the product map data using a statistical approach, with the results presented in a confusion matrix. Sample weights are used to compensate for the unbalanced selection probabilities of individual sample units in the stratified sampling approach. Several accuracy measures are calculated to assess the thematic accuracy of the CLMS product. These reporting measures include:

- **User's Accuracy (per product class, UA):** Indicates the probability that a sample unit classified as a certain class in the product actually belongs to that class on the ground.
- **Producer's Accuracy (per product class, PA):** Indicates the probability that a sample unit belonging to a certain class on the ground is correctly classified in the product.
- **Overall Accuracy (OA):** Indicates the proportion of correctly classified sample units across all classes.

- **Margin of Error (MoE):** The margin of error, representing the standard deviation at a 95% confidence level, is calculated for user's accuracy, producer's accuracy, and overall accuracy. This provides an estimate of the uncertainty associated with the accuracy measures.

$$MoE = z \times SE$$

SE is the Standard Error of the accuracy estimate, and z is the z-score corresponding to the desired confidence level, approximately 1.96 for 95% confidence level.

- **F1 Score (per product class i):** The F1 Score is a harmonic mean of user's accuracy and producer's accuracy for each product class. It provides a single measure of accuracy that balances the trade-off between both accuracies.

$$F1\ Score = 2 \times \frac{UA_i \times PA_i}{UA_i + PA_i}$$

Since the CLMS validation framework uses the same sample units for different CLMS products the strata and the mapped classes are not the same, and standard stratified estimators (Olofsson et al., 2014) are not suitable for calculation of overall, user's and producer's accuracy. Instead indicator functions and stratified estimators described by Stehman (2014) are used to calculate accuracies and their variances. The indicator functions are used to account for that sample units are selected from strata different than the map classes. Indicator function for overall accuracy is defined as:

$$y_u = \begin{cases} 1 & \text{if unit } u \text{ is classified correctly} \\ 0 & \text{if unit } u \text{ is classified incorrectly} \end{cases}$$

Overall accuracy is then calculated as a sample mean using a stratified estimator Stehman (2014):

$$\hat{\bar{Y}} = \sum_{h=1}^H N_h^* \bar{y}_h / N$$

where $\bar{y}_h = \sum_{u \in h} y_u / n_h^*$ is the sample mean of the y_u values in stratum h , $u \in h$ indicates that sample unit u was selected from stratum h and H denotes the number of strata. N is the number of all possible units in the sample frame (population), N_h^* is the number of possible units and n_h^* the selected sample units in stratum h . An estimator for the variance of $\hat{\bar{Y}}$ is provided in Stehman (2014) Equitation 25 and 26.

User's accuracy and producer's accuracy require different indicator functions for y_u and x_u .

For user's accuracy:

$$y_u = \begin{cases} 1 & \text{if unit } u \text{ is classified correctly and is map class } k \\ 0 & \text{otherwise} \end{cases}$$

and

$$x_u = \begin{cases} 1 & \text{if unit } u \text{ is map class } k \\ 0 & \text{otherwise} \end{cases}$$

for producer's accuracy:

$$y_u = \begin{cases} 1 & \text{if unit } u \text{ is classified correctly and has class } k \text{ in the validation data} \\ 0 & \text{otherwise} \end{cases}$$

and

$$x_u = \begin{cases} 1 & \text{if unit } u \text{ has class } k \text{ in the validation data} \\ 0 & \text{otherwise} \end{cases}$$

User's and producer's accuracies are then calculated using a combined ratio estimator from Stehman (2014) Equation 27:

$$\hat{R} = \frac{\sum_{h=1}^H N_h^* \bar{y}_h}{\sum_{h=1}^H N_h^* \bar{x}_h}$$

where \bar{y}_h and \bar{x}_h are the sample means of y_u and x_u in the stratum h . The variance estimator for \hat{R} is provided in Stehman (2014) Equation 28.

In addition to accuracy metrics based on the weighted confusion matrix, unweighted confusion matrices with raw sample unit counts are provided. These offer insights into inter-class confusion, especially for rare classes with low sample weights and where the actual performance may not be well reflected in the weighted result. To avoid confusion with the statistical correct weighted accuracy metrics, the producer's and user's accuracy based on the unweighted confusion matrix are labelled additionally as "Unweighted" and calculated as:

$$\text{Unweighted UA} = \frac{\text{Number of sample units correctly classified and with map class } k}{\text{Total number of sample units classified as map class } k}$$

$$\text{Unweighted PA} = \frac{\text{Number of sample units correctly classified and with validation class } k}{\text{Total number of sample units with validation data class } k}$$

3.2 Usability

The following usability assessment are done using the CLCplus BB 2018 product:

- Product and metadata accessibility and alignment with FAIR principles.
- Checking product compliance with generic product requirements for the potential use case "Facilitation of independent assessments and the modelling of carbon pool dynamics according to LULUCF regulation".
- Assessment of the CLMS Portal's accessibility using various methods and tools to evaluate different aspects.
- Documentation & metadata completeness: Review of Product User Manuals (PUM) and Algorithm Theoretical Basis Document (ATBD).

To ensure the CLCplus BB 2018 product metadata and datasets comply with FAIR principles, **evaluations are conducted using a Digital Object Identifier (DOI) or permanent Uniform Resource Locator (URL)** with three specific tools: FAIR Enough (FAIR Enough, 2022), FAIR-checker (FAIR-Checker, 2024) and F-UJI (F-UJI, 2024). These tools often identify overlapping issues, but their comparative outputs help emphasize different FAIR principles such as Findability, Accessibility, Interoperability, and Reusability. This analysis helps pinpoint areas for improvement, listing non-compliant criteria and suggesting potential solutions. The assessment of the CLMS Portal emphasizes evaluating accessibility to ensure that users can easily access and interact with CLMS products through the Portal. This assessment, focusing on performance and user interaction, is conducted post-publication using a variety of methods and tools. These tools

check compliance with web accessibility standards, analyse user navigation, evaluate user experiences during login, verify content format availability, measure response times, and ensure the use of open, standardized protocols. The assessment also includes testing across different browsers and devices to test consistent performance and responsiveness.

The product requirements check whether the product specifications align with a specific use case. The process begins by identifying the use case and its specific requirements, such as temporal and spatial resolution, thematic accuracy, and data accessibility. These requirements are organized in a product requirements check table and evaluated against the product documentation and metadata as published on the CLMS Portal. Compliance observations are recorded, along with any identified gaps where the product does not fully meet user expectations or where the source data used does not allow compliance to be confirmed.

The document review approach enhances the ATBD and PUM of the CLMS product by assessing various criteria against standards and best practices for quality, format, and depth. In this case, no ATBD was provided, and the review was therefore limited to the PUM. It ensures logical content structure, clear language, and high-quality visuals. The review, from preliminary drafts to final versions, uses tables to systematize and standardize evaluations, incorporating a scoring system and targeted checks. If the documents predate specific templates, certain assessments are omitted. The process is documented in detail, providing a comprehensive record of the evaluations and areas for improvement.

4 Results

4.1 Thematic Accuracy

The thematic accuracy results are described at the two reporting levels: EEA38 and BGR.

4.1.1 EEA38

The thematic accuracy evaluation shows **an overall accuracy of the CLCplus BB 2018 raster layer of 85.2% (0.5% Margin of Error) for the plausibility approach** and 77.2 % (0.6%) for the blind validation approach (Table 7). The blind validation results are in line with the overall accuracy values recorded during the internal production assessment of 77.5% (0.4%), while the plausibility results are lower than the previously published 91.9% (0.3%) (Copernicus Land Monitoring Service, 2022). **The targeted overall accuracy of the CLCplus BB raster of >90% could thus not be confirmed.**

Table 7: Overall thematic accuracy results at EEA38 level

Method	Overall Accuracy [%]	Margin of Error [%]
Blind validation approach	77.2	0.6
Plausibility validation approach	85.2	0.5

Accuracies improve during the plausibility checks, with more classes approaching or exceeding the requested 85% class accuracy (Table 8). The class-specific accuracies of the periodically herbaceous class (7), water (10) and snow and ice (11) have user's or producer's accuracies higher than the required 85% in the blind validation results. Especially, the classes low-growing woody plants (5), lichens and mosses (8) and non- and sparsely-vegetated (9) improved considerably during the plausibility checks. The higher user's accuracy (UA) compared to producer's accuracy (PA) for the classes periodically herbaceous (7), lichens and mosses (8) and non- and sparsely-vegetated (9) indicate that those classes are underestimated in the CLCplus product. The lower PA indicates that the number of missed pixels in these classes is higher than the number of falsely classified pixels in the map. The MoE is below the targeted 5% for all classes except lichens and mosses (8), which relates to the combination of lower accuracy and lower number of sample units.

The confusion matrix shows the number of samples per class (Table 9). It provides more information on the main class confusions identified during the plausibility analysis. The green diagonal line indicates the matches between CLMS product and validation sample. One unexpected confusion is between sealed (1) and permanent herbaceous areas (6). The very high producer's accuracy (unweighted) of 90.6% contrasts with the lower user's accuracy of 73.5%. There are many areas where well classified small urban structures and surrounding landscape are very well captured (Figure 5). However, visual data checks showed, that this reported confusion of often caused by fragmented urban settlements or linear infrastructures like roads, which are difficult to capture at 10m spatial resolution and the strong spectral response from sealed surfaces (Figure 6 and Figure 7). There are good examples of differentiation between small adjacent areas of broadleaved and coniferous forest, and the transition to herbaceous

CLCplus BB classes

- 1: Sealed
- 2: Woody – needle leaved trees
- 3: Woody – Broadleaved deciduous trees
- 4: Woody – Broadleaved evergreen trees
- 5: Low-growing woody plants (bushes, shrubs)
- 6: Permanent herbaceous
- 7: Periodically herbaceous
- 8: Lichens and mosses
- 9: Non- and sparsely-vegetated
- 10: Water
- 11: Snow and ice

areas (Figure 8). Still, high confusion occurs among some vegetation-related classes. Low growing woody plants (5) show confusion with larger growing deciduous trees (3) and permanent herbaceous areas (6) (Figure 9). Sparse vegetation (9) also contributes to misclassifications with sealed (1) and permanent herbaceous (6). Permanent herbaceous (6) has confusion with all other classes, except snow and ice (11). Lichens and mosses (8) are especially confused with permanent herbaceous vegetation (6) and non- and sparsely-vegetated (9) areas. Lichens and mosses often grow in complex patterns with rocks, grasses, dwarf shrubs, difficult to assess using satellite image pixels and is often even difficult to map without further ancillary information from very high-resolution images (Figure 10). Other classes like water (10) and snow and ice (11) have very high classification accuracy, showing minimal confusion.

Table 8: Thematic accuracy results at EEA38 per CLCplus BB class

Product Class	Blind Validation approach					Plausibility validation approach				
	UA [%]	MoE [%]	PA [%]	MoE [%]	F1 Score [%]	UA [%]	MoE [%]	PA [%]	MoE [%]	F1 Score [%]

		Producer's Accuracy Unweighted	90.6%	87.7%	84.8%	81.1%	77.7%	72.7%	86.6%	81.4%	76.2%	96.7%	99.4%		82.5%

4.1.2 BGR

The Overall Accuracy (OA) per BGR shows regional variation (Table 10). Accuracies >90% were achieved in the plausibility approach for the Arctic region (ARC). Most of the other BGRs are slightly below 90%, with the regions Anatolian, Boreal, Mediterranean and Tropical lower than 85%. Tropical has the lowest accuracy of 74.4%. The Margin of Error (MoE) is below 5% for all BGRs, which indicates robust accuracy estimates.

The accuracies per class (Table 11) show a similar picture at BGR level as for the EEA38. The F1 Score for sealed (1) is below 70% for seven of the twelve BGRs (Alpine, Anatolian, Arctic, Black Sea, Boreal, Steppic, Tropical) with high MoE. Low-growing woody plants (5) is below 50% within six BGRs, all with a MoE >5%. The rare class lichens and mosses (8) occurs in three BGRs, which F1 Scores between 39.6 and 72.6%. Water (10), snow and ice (11) and woody – needle leaved trees (2) have the highest accuracies reaching values >90%. The regions Atlantic and Continental have very good accuracy results (up to 96.5% F1 score) for the majority of the classes occurring in these regions, while only sealed (1), low-growing woody plants (5), permanent herbaceous (6) and non- and sparsely-vegetated (9) are below 85% for UA and PA. Within the Tropical region, only water (10) is exceeding a F1 score of 85%. Periodically herbaceous areas (7) are well detected in most of the BGRs with at least PA or UA above or close to 90%, except in Mediterranean, Pannonian and Tropical.

The confusion matrix with sample counts (Table 12) shows similar class confusion in the BGRs as already observed at EEA38-level. Noteworthy is the high number of sample units identified as sealed (1) in the validation data that were correctly classified as sealed in most BGRs. The unweighted producer's accuracy for this class exceeds 90% in most BGR (Table 12) and is considerable higher than the weighted producer's accuracy (Table 11). This difference is due to the confusion with classes that have much higher sampling weights, particularly the large permanent herbaceous class (6). Confusion between low-growing woody plants (5), permanent herbaceous (6) and periodically herbaceous (7), is evident in several regions (Pannonian, Continental, Steppic, Mediterranean) indicating the difficulty to distinguish between these classes.

Table 10: Overall Accuracy per Biogeographical Region

Biogeographical Region	Blind		Plausibility	
	Overall Accuracy [%]	Margin of Error [%]	Overall Accuracy [%]	Margin of Error [%]
Alpine (ALP)	81.0	1.7	86.1	1.6
Anatolian (ANA)	77.7	2.7	83.6	2.4
Arctic (ARC)	79.9	4.1	90.2	3.0
Atlantic (ATL)	79.4	1.4	87.7	1.1
Black Sea (BLS)	85.1	1.9	85.3	1.9
Boreal (BOR)	82.9	1.8	84.7	1.7
Continental (CON)	86.7	1.0	87.8	1.0
Macaronesia (MAC)	59.6	4.8	86.8	3.6
Mediterranean (MED)	65.9	1.4	81.1	1.1
Pannonian (PAN)	85.3	1.6	89.8	1.4
Steppic (STE)	85.0	2.2	85.0	2.2
Tropical (TRO)	73.8	3.0	74.4	3.0

Green = 90% or higher, Yellow = 85-89.9%, Red = MoE >5%

Table 11: Class accuracies per BGR - Plausibility approach

BGR	Class	Name	UA [%]	MoE [%]	PA [%]	MoE [%]	F1 Score [%]

4.2 Usability

The evaluation of the CLCplus BB 2018 dataset's alignment with FAIR principles was assessed using various automated tools. The dataset was tested using FAIR Enough, FAIR-checker, and F-UJI, with scores expressed as percentages of a maximum of 100%. **The results were as follows: FAIR Enough data at 59.09%, FAIR Enough metadata at 91.25%, FAIR-checker at 70.83%, and F-UJI at 77%.** The evaluation highlighted strengths and identified improvement areas to enhance FAIR compliance. For Findability, the adoption of globally recognized Persistent Identifiers and the use of interoperable ontologies for metadata are recommended. To improve Reusability, adding comprehensive data descriptors, recognized licenses, and formal provenance information is advised. For Accessibility, standardizing and enhancing data access information and URLs in metadata will support compliance.

The Annex 4 to the Tender Specifications (EEA, 2023) does not specifically define user requirements but **includes information for the use case "Facilitation of independent assessments and the modelling of carbon pool dynamics according to LULUCF regulation". This generic product requirements check evaluates the product's alignment with this use case.** Key requirements assessed include spatial and thematic accuracy, timely updates, and alignment with LULUCF categories. The assessment involves comparing the product attributes against the specified requirements using references such as product manuals and validation reports. It reveals that the CLCplus BB 2018 meets most of the needs assessed like spatial resolution and data accessibility but noted that temporal coverage is partially aligned. The source data used shows limitations that prevent a full assessment of product attributes against the specified requirements.

The CLMS Portal underwent thorough testing to assess its functionality, accessibility, performance, and usability. Accessibility was evaluated using tools like WAVE and Lighthouse, which highlighted strong compliance with web standards and identified areas for improvement in performance and navigation. User journey mapping and cross-browser compatibility checks ensured a reliable user experience across various devices and browsers. The tests revealed the portal's strong accessibility with notable compliance, although performance optimizations were suggested. Secure and open access options for data downloads were confirmed through user authentication tests. The content is broadly accessible in multiple formats, ensuring usability across different platforms. Overall, the portal meets critical web and data access standards, ensuring a functional and user-friendly environment.

The documentation review for CLCplus BB 2018 focused on the PUM, as an ATBD was unavailable. The PUM, published on 30.09.2022, was evaluated using a 23-item checklist before the implementation of standardized templates. **This review highlighted the document's generally good structure** but noted several areas needing improvement such as referencing external standards, use case presentation, and formatting consistency. **Significant findings from the review included the need for more detailed references to standards, updated abbreviations, and clearer tables.** The review also suggested enhancing the product quality section and adding a dedicated section for use cases to better guide users. Issues with page numbering and formatting inconsistencies were also noted, emphasizing the need for a more streamlined presentation to improve user accessibility and understanding of the document.

5 Conclusions and Recommendations

5.1 Thematic Accuracy

The new CLMS validation framework methods and tools are used for the first time to validate the CLCplus Backbone raster product for 2018. The validation areas defined within the cross-cutting validation framework and applied to generate validation data for CLCplus BB in a synergistic blind and plausibility approach. **Thematic accuracy is assessed using a statistically sound methodology, leveraging available reference and supportive data across different reporting units.** It was essential that the usage of the LUCAS data in the CLMS productions was recorded (including LUCAS sample locations used) and provided to enable independent validation. **Due to the heavy usage of LUCAS 2018 in the CLCplus production process, any point in the sampling frame that was also part of the LUCAS 2018 survey has been replaced.** Future validation efforts could be minimised if LUCAS reference data is constrained in the CLMS Backbone production.

The VHR image data 2018 is used in the visual validation process. It provides VHR multispectral products (with a spatial pixel resolution from 2 to 4 meters) for the CLMS reference years 2018. Especially for regions without aerial orthophoto imagery this data set is the prime image reference. However, due to the applicable spatial resolution it has limitations for the analysis of land cover class relevant features. For some regions higher resolution data (<2m) could support the validation process, especially for regions with poor or no access to digital aerial photography as alternative VHR image data source. **A stronger inclusion of time-series information could also aid the interpretation process for upcoming products,** especially for temporally defined land cover classes.

The thematic validation results show good results. However, the target overall accuracy of >90% at EEA38 level is not met. Classes that are difficult to map and validate visually show a significant improvement in plausibility checks as compared to the blind validation, such as low-growing woody plants (5), lichens and mosses (8) and non- and sparsely-vegetated (9). Such classes can be better assessed if a priori map class information is considered during the visual interpretation. The class-specific accuracies show the expected confusion between low-growing woody plants (5), permanent herbaceous (6) as well as periodically herbaceous areas (7). **These land cover classes are difficult to map due to similar spectral behaviour and their temporal/seasonal dynamics make the visual interpretation of reference data challenging.** This may also contribute to the regional differences at the BGR level. **Weaker classification results are seen within the regional assessments of the Mediterranean (MED) and Tropical (TRO) BGRs, which show challenges distinguishing certain classes,** especially low-growing woody plants (5), permanent herbaceous (6), and periodically herbaceous (7). **The Arctic (ARC) region is the only one to achieve >90% accuracy, lowest accuracy is observed in the Tropical (TRO) DOM region.**

Consistency checks between the CLCplus BB 2018 and 2021 are not explicitly performed for this report. However, both products show very similar validation results and patterns (see D7-2 Validation Report CLCplus Backbone 2021). Further work may be helpful to check the time series consistency and focus on areas of change between 2018 and 2021.

5.2 Usability

To support user uptake and ensure the CLCplus BB 2018 product meets key expectations for usability, a structured assessment was carried out. This evaluation focuses on critical aspects such as FAIR compliance, fitness for a specific use case, platform accessibility, and the completeness of product documentation.

The method used has limitations and does not allow a full assessment of CLCplus BB 2018 against the specified requirements. Despite this, the evaluation indicates that the product meets key needs such as spatial resolution and data accessibility, while temporal coverage is partially aligned with the LULUCF use case requirements.

The CLMS Portal is commendable for its accessibility and usability, meeting essential requirements like data access and multi-format availability. To improve further, streamlined navigation and benchmark comparability testing could provide insights into performance enhancements.

The PUM review indicates it is comprehensive yet requires improvements in clarity, consistency, and user guidance. Recommendations include standardizing formatting, adding conversion examples for external standards, renumbering pages, and introducing a dedicated "Use Cases" section. Adhering to the CLMS PUM Template by structuring content, simplifying detailed sections, and standardizing terminology would make the document more accessible and informative for diverse users.
